Computer Networks

Transport Layer – Pipelined Protocols

Performance of rdt3.0

- rdt3.0 is correct, but performance stinks
- e.g.: 1 Gbps link, 15 ms prop. delay, 8000 bit packet:

$$D_{trans} = \frac{L}{R} = \frac{8000 \text{ bits}}{10^9 \text{ bits/sec}} = 8 \text{ microsecs}$$

- U_{sender} : *utilization* – fraction of time sender busy sending

$$U_{\text{sender}} = \frac{L / R}{RTT + L / R} = \frac{.008}{30.008} = \mathbf{0.00027}$$

- *if $RTT=30 \text{ msec}$, 1KB pkt every 30 msec: 33kB/sec throughput over 1 Gbps link!!!*
- ❖ Network protocol limits use of physical resources!
- ❖ Need to identify the cause and fix it: *why utilization is so low?*

Stop-and-wait Operation of rdt3.0

$$U_{\text{sender}} = \frac{L / R}{RTT + L / R} = \frac{.008}{30.008} = 0.00027$$

How to improve channel utilization?

Pipelined Protocols

pipelining: sender allows multiple, “in-flight”, yet-to-be-acknowledged pkts

- range of sequence numbers must be increased
- buffering at sender and/or receiver

(a) a stop-and-wait protocol in operation

(b) a pipelined protocol in operation

- No more ‘stop-and-wait’!
- Generic form of ‘*sliding window*’ protocols

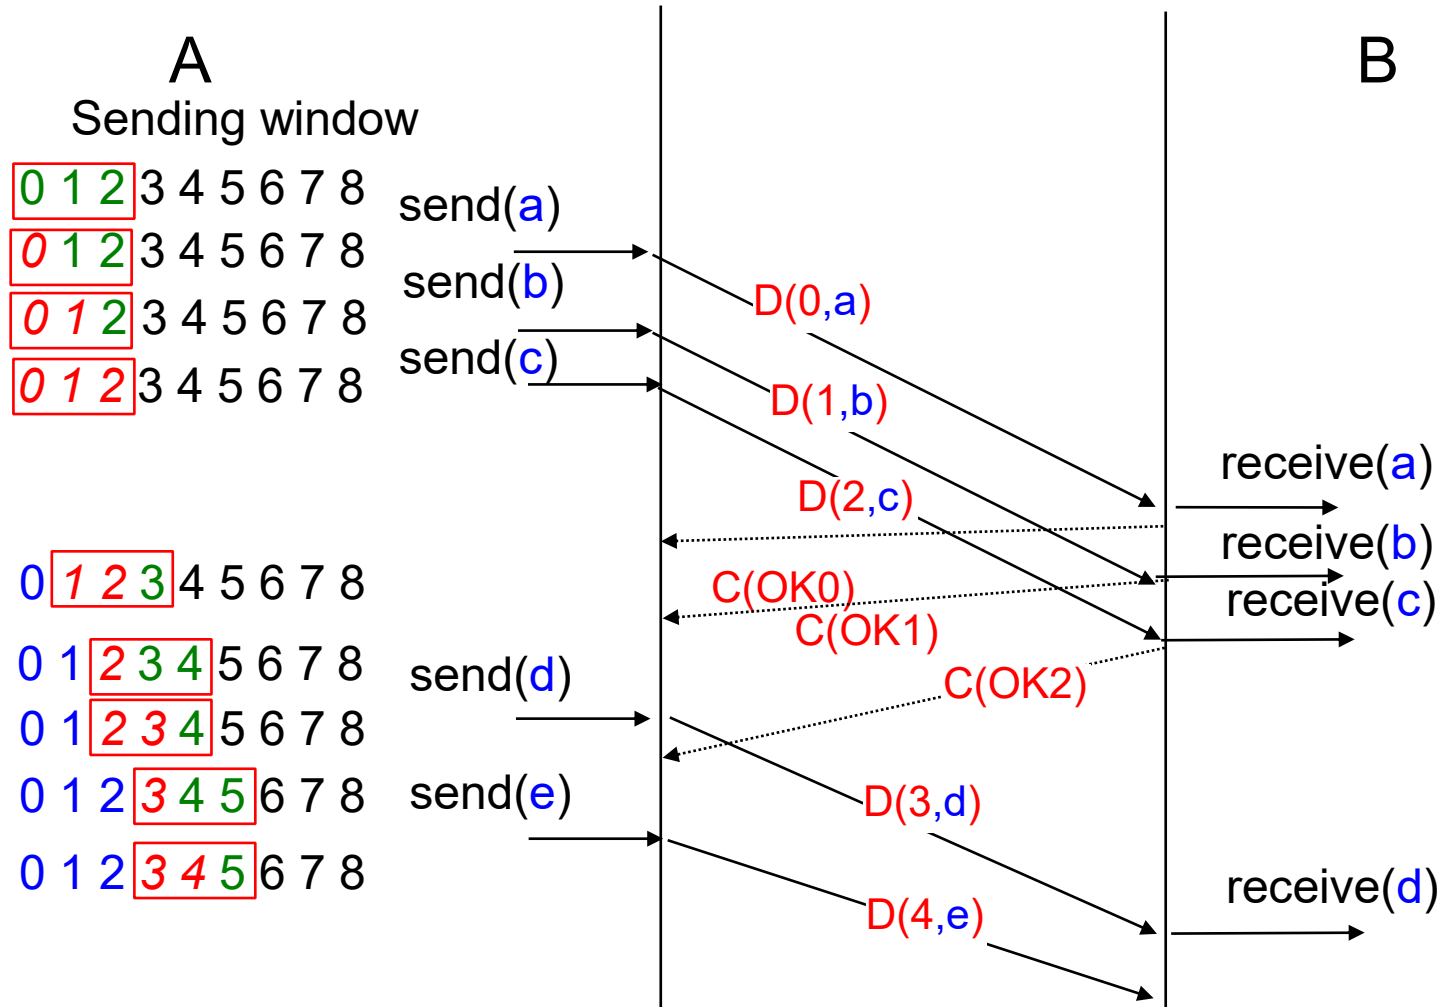

Sliding Window Protocol

- To avoid 'stop-and-wait' behavior
 - Sender keeps a list of all the segments that it is allowed to send: *sending_window*
 - Receiver also maintains a receiving window with the list of acceptable sequence numbers: *receiving_window*
 - During data transfer the windows appear to be sliding across segment sequential numbers
- Sender and receiver must use compatible windows (e.g. negotiated during connection establishment phase)

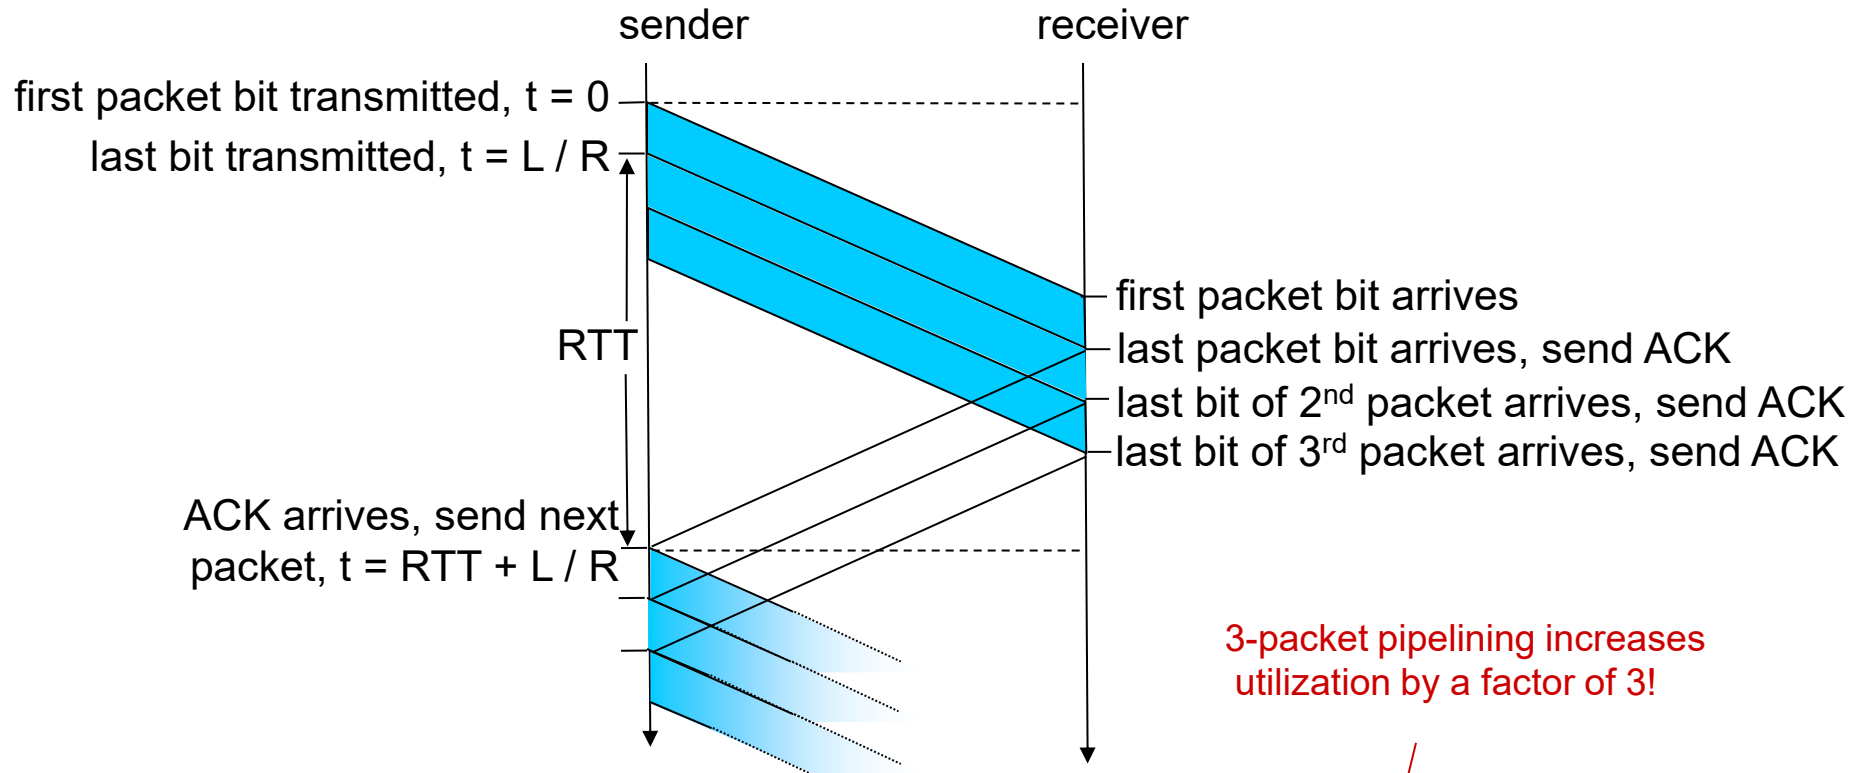

Sliding Windows Example

- Sending and receiving window size : 3 segments

Pipelining: Increased Utilization

3-packet pipelining increases utilization by a factor of 3!

$$U_{\text{sender}} = \frac{3L / R}{RTT + L / R} = \frac{.0024}{30.008} = 0.00081$$

rdt with Pipelined Protocol

- Problem: how to provide reliable data transfer with a pipelined protocol?
- Basic solutions:
 1. *Go-Back-N*
 - simple implementation (particularly on receiving side)
 - throughput will be limited when losses occur
 2. *Selective Repeat*
 - more difficult from an implementation viewpoint
 - throughput can remain high when limited losses occur

Pipelined Protocols: Overview

Go-back-N:

- sender can have up to N unack'ed packets in pipeline
- receiver only sends *cumulative ack*
 - doesn't ack packet if there's a gap
- sender has timer for oldest unack'ed packet
 - when timer expires, retransmit *all* unack'ed packets

Selective Repeat:

- sender can have up to N unack'ed packets in pipeline
- rcvr sends *individual ack* for each packet
- sender maintains timer for each unack'ed packet
 - when timer expires, retransmit only that unack'ed packet

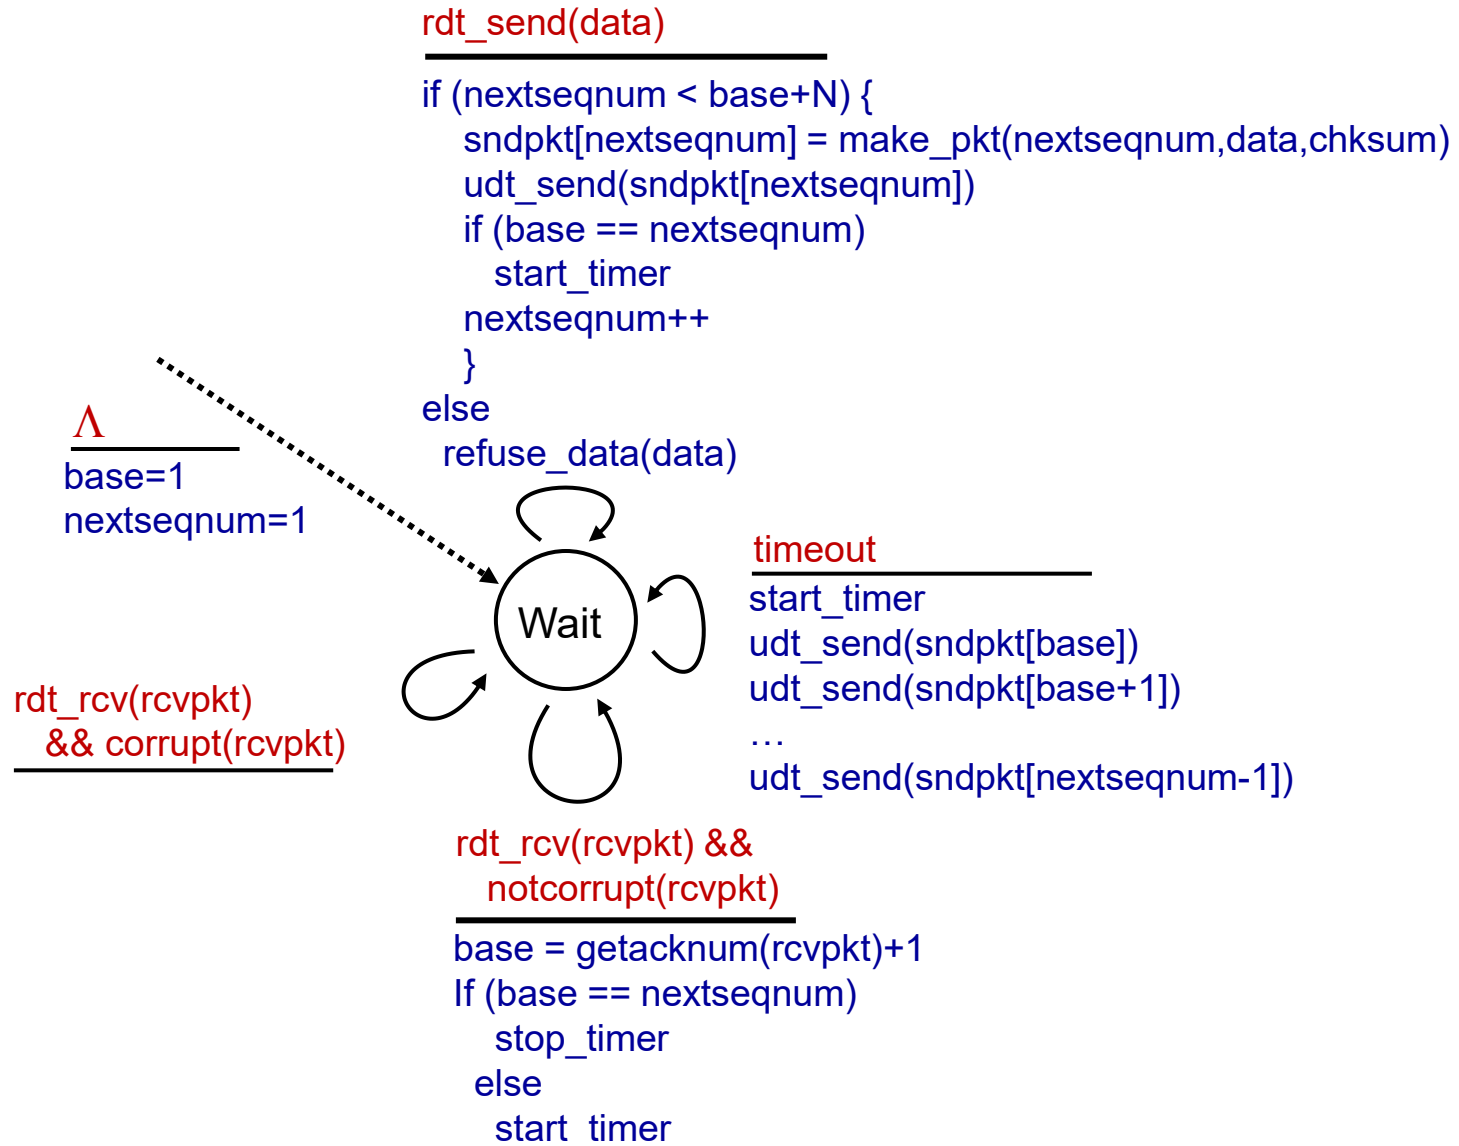

Go-Back-N: Sender

- k-bit seq # in pkt header
- “window” of up to N, consecutive unack’ed pkts allowed

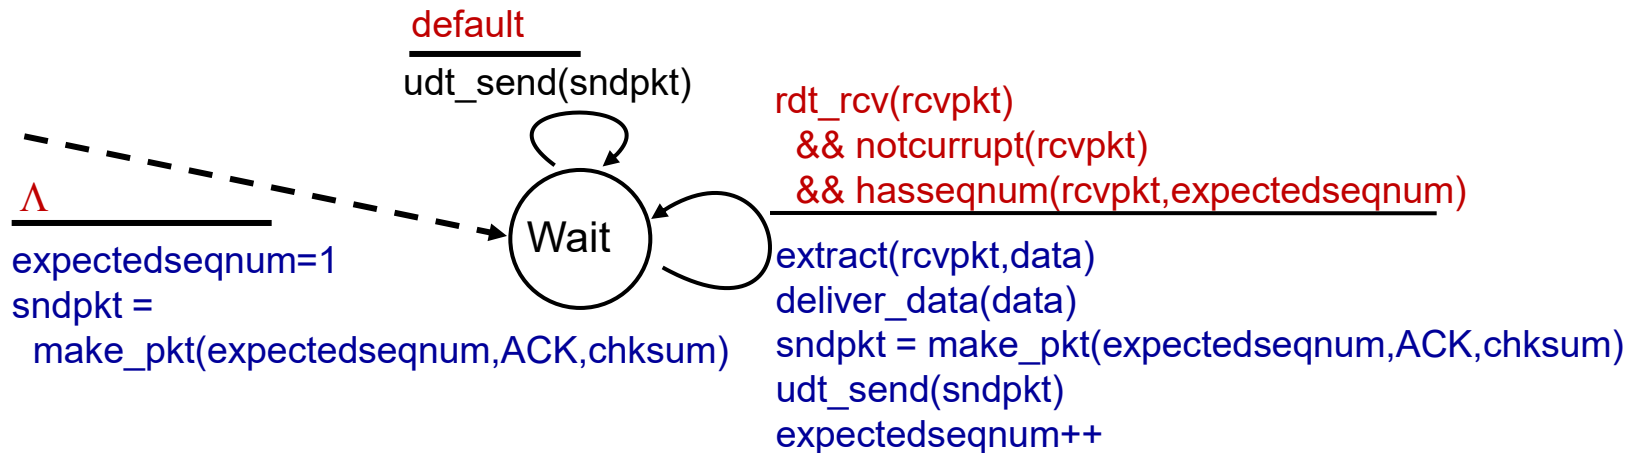

- ❖ ACK(n): ACKs all pkts up to, including seq # n - “*cumulative ACK*”
 - may receive duplicate ACKs (see receiver)
- ❖ timer for oldest in-flight pkt
- ❖ *timeout(n)*: retransmit packet n and all higher seq # pkts in window

GBN: Extended FSM for Sender

GBN: Extended FSM for Receiver

ACK-only: always send ACK for correctly-received pkt with highest *in-order* seq #

- may generate duplicate ACKs
- need only remember **expectedseqnum**
- out-of-order pkt:
 - discard (don't buffer): *no receiver buffering!*
 - re-ACK pkt with highest in-order seq #

GBN in Action

sender window (N=4)

0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8

sender

send pkt0

send pkt1

send pkt2

send pkt3

(wait)

rcv ack0, send pkt4

rcv ack1, send pkt5

ignore duplicate ACK

pkt 2 timeout

send pkt2

send pkt3

send pkt4

send pkt5

receiver

receive pkt0, send ack0

receive pkt1, send ack1

receive pkt3, discard,
(re)send ack1

receive pkt4, discard,
(re)send ack1

receive pkt5, discard,
(re)send ack1

rcv pkt2, deliver, send ack2

rcv pkt3, deliver, send ack3

rcv pkt4, deliver, send ack4

rcv pkt5, deliver, send ack5

Selective Repeat

- receiver *individually* acknowledges all correctly received pkts
 - buffers pkts, as needed, for eventual in-order delivery to upper layer
- sender only resends pkts for which ACK not received
 - sender timer for each unACK'ed pkt
- sender window
 - N consecutive seq #'s
 - limits seq #'s of sent, unACK'ed pkts

Selective Repeat: sender, receiver Windows

Selective Repeat

sender

data from above:

- if next available seq # in window, send pkt

timeout(n):

- resend pkt n, restart timer

ACK(n) in [sendbase, sendbase+N]:

- mark pkt n as received
- if n smallest unACKed pkt, advance window base to next unACKed seq #

receiver

pkt n in [rcvbase, rcvbase+N-1]

- ❖ send ACK(n)
- ❖ out-of-order: buffer
- ❖ in-order: deliver (also deliver buffered, in-order pkts), advance window to next not-yet-received pkt

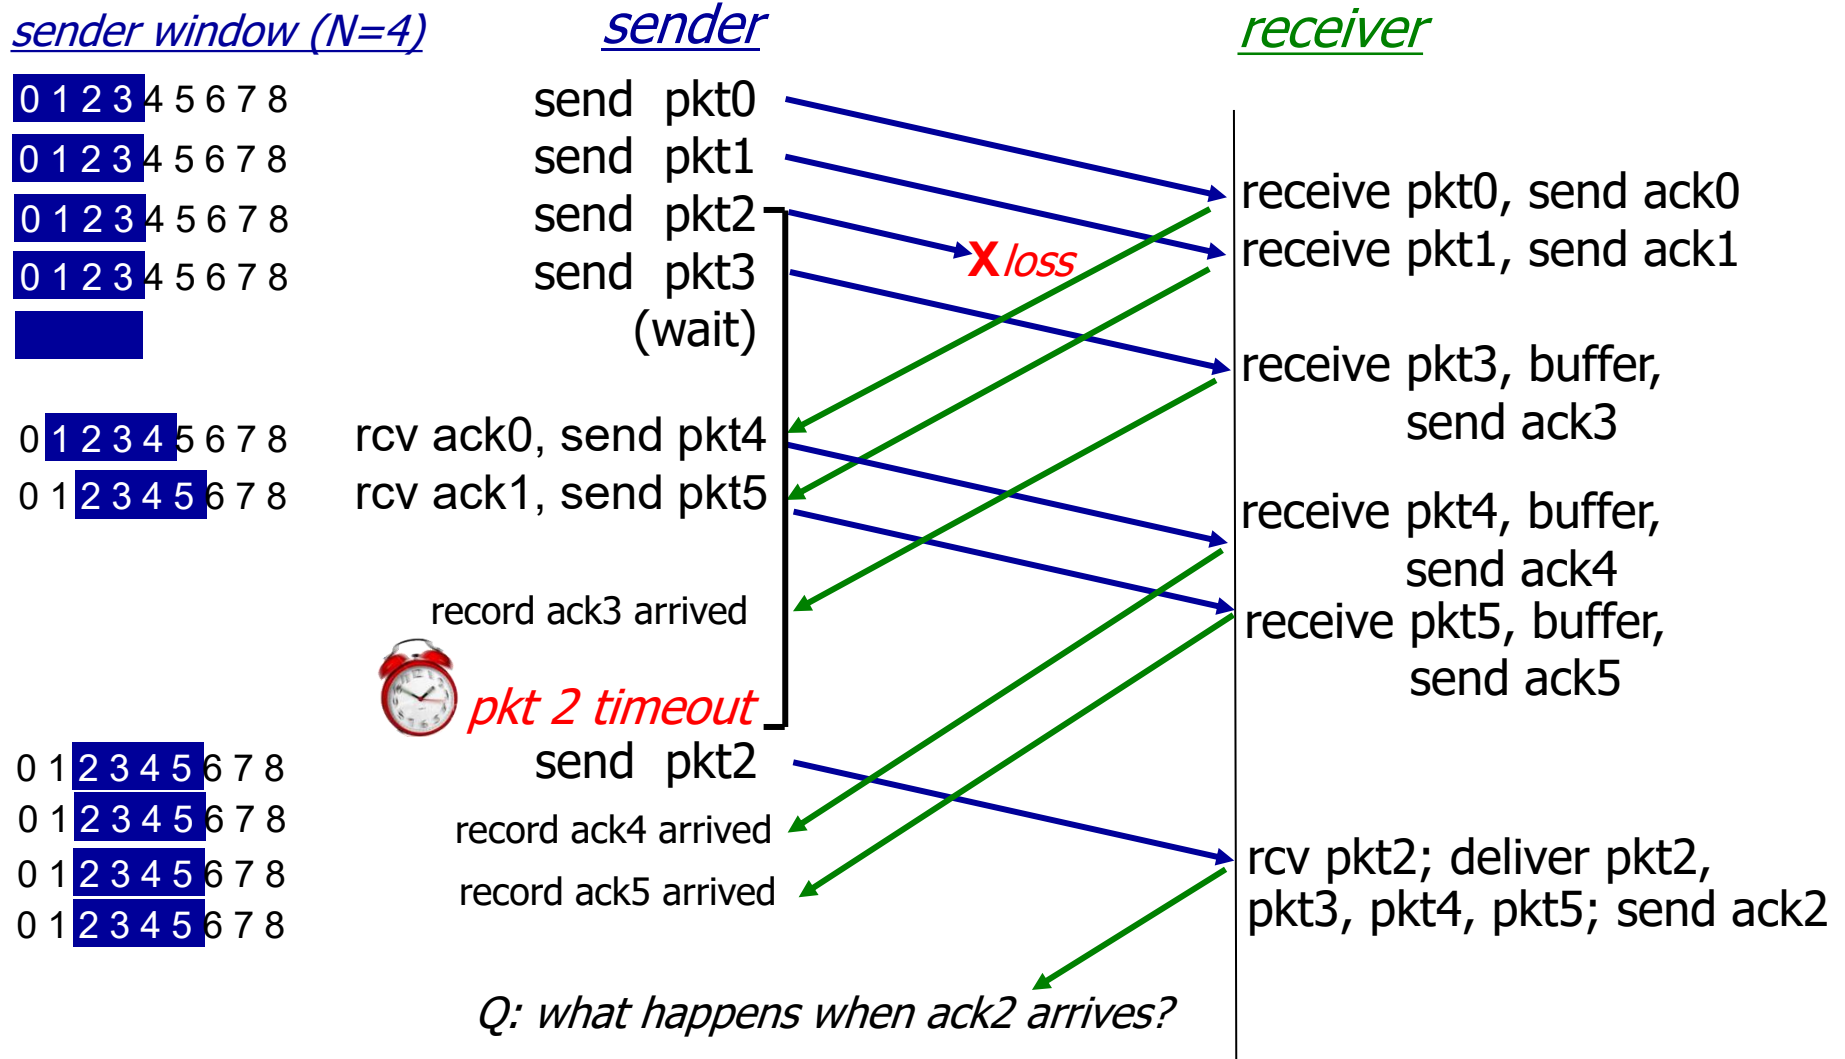

pkt n in [rcvbase-N, rcvbase-1]

- ❖ ACK(n)

otherwise:

- ❖ ignore

Selective Repeat in Action

Selective Repeat: Dilemma

example:

- seq #'s: 0, 1, 2, 3
- window size=3

- ❖ receiver sees no difference in two scenarios!
- ❖ duplicate data accepted as new in (b)

Q: what relationship between seq # size and window size to avoid problem in (b)?

sender window
(after receipt)

receiver window
(after receipt)

*receiver can't see sender side.
receiver behavior identical in both cases!
something is (very) wrong!*
